Working Papers

"Industry Shakeouts after an Innovation Breakthrough" (Job Market Paper)

After a technological breakthrough, conventional wisdom suggests that the number of active firms first surges, and then sharply declines, in a "shakeout". This paper challenges that notion with new empirical evidence from across the economy, revealing that shakeouts are the exception, not the rule. I develop a statistical method to identify breakthroughs by tracking sustained anomalies in net firm entry rates, offering a robust alternative to narrative-driven approaches and applicable to all industries. The method reliably aligns with well-documented breakthroughs and remains consistent across various validation tests. Moreover, the analysis uncovers a novel trend: the number of breakthroughs have been declining over time. Using a dynamic model, I show that the absence of shakeouts reflects breakthroughs primarily occurring in industries with low returns to scale and modest learning effects, shifting the narrative on how innovation shapes industry structure, particularly over the past forty years in the

"Much ado about Property Rights: China's Agricultural Wedges" (with Wei Lin & Shijian Yang)

Recent work in misallocation centers on estimating the effects of removing policy distortions on aggregate productivity and output. However, the efficacy of reversing distortions on allocation strongly depends on whether the agents affected have market incentives and on the relationships between the individual distortions. We show that a 2003 Chinese land law, which abolished a decades-old policy of egalitarian land reallocation and allowed land rentals, improved allocation among farmers that sell to the market, but not in general. Using a rich panel dataset of the production and sales behavior of Chinese farmers, we decompose the wedges by factor input. We quantify the impact of the 2003 land law on individual factor distortions and calculate the impact of the law on output. We show that impact of the law is relatively small compared to potential welfare gains from the complete elimination of individual wedges.
